What is Linear Programming?

Definition

In general, linear Programming is optimising a linear function subject to a set of linear inequalities

What is Linear Programming?

Definition

In general, linear Programming is optimising a linear function subject to a set of linear inequalities

- Optimising a function is finding the *minimum* or *maximum* value of a function

What is Linear Programming?

Definition

In general, linear Programming is optimising a linear function subject to a set of linear inequalities

- ▶ Optimising a function is finding the *minimum* or *maximum* value of a function
- ▶ A linear function... e.g. $5 + 3x + 4y$

What is Linear Programming?

Definition

In general, linear Programming is optimising a linear function subject to a set of linear inequalities

- ▶ Optimising a function is finding the *minimum* or *maximum* value of a function
- ▶ A linear function... e.g. $5 + 3x + 4y$
- ▶ A linear inequality... e.g. $5x + 3y \leq 10$, $3 + 5y \geq 4z$

Linear Programming - Example

Linear Programs arise in a variety of practical applications...

Example

A publisher has orders for 400 copies of a certain text from Bristol (b) and 600 copies from Leeds(l). The company has 700 copies in a warehouse in Birmingham (B) and 800 copies in a warehouse in London (L). It costs £5 to ship a text from Birmingham to Bristol, but it costs £4 to ship it to Leeds. It costs £10 to ship a text from London to Bristol, but it costs £8 to ship it from London to Leeds. How many copies should the company ship from each warehouse to Bristol and Leeds to fill the order at the least cost?

Linear Programming - Example

Example

A publisher has orders for 400 copies of a certain text from Bristol (b) and 600 copies from Leeds(l). The company has 700 copies in a warehouse in Birmingham (B) and 800 copies in a warehouse in London (L). It costs £5 to ship a text from Birmingham to Bristol, but it costs £4 to ship it to Leeds. It costs £10 to ship a text from London to Bristol, but it costs £8 to ship it from London to Leeds. How many copies should the company ship from each warehouse to Bristol and Leeds to fill the order at the least cost?

Linear Programming - Example

$$x + y \geq 400$$

$$w + z \geq 600$$

► Available Stock

$$x + w \leq 700$$

$$y + z \leq 800$$

► Non-negative Inequalities

$$x \geq 0, y \geq 0, w \geq 0, z \geq 0$$

Linear Programming - Example

Example

A publisher has orders for 400 copies of a certain text from Bristol (b) and 600 copies from Leeds(l). The company has 700 copies in a warehouse in Birmingham (B) and 800 copies in a warehouse in London (L). It costs £5 to ship a text from Birmingham to Bristol, but it costs £4 to ship it to Leeds. It costs £10 to ship a text from London to Bristol, but it costs £8 to ship it from London to Leeds. How many copies should the company ship from each warehouse to Bristol and Leeds to fill the order at the least cost?

Linear Program - Non-standard form

$$\text{minimise} \quad 5x + 10y + 4w + 8z$$

$$\text{subject to} \quad x + y \geq 400$$

$$w + z \geq 600$$

$$x + w \leq 700$$

$$y + z \leq 800$$

$$x \geq 0, y \geq 0, w \geq 0, z \geq 0$$

Linear Programming - Example

Linear Program - Matrix Representation

minimise $5x + 10y + 4w + 8z$

subject to $1x + 1y + 0w + 0z \geq 400$

$$0x + 0y + 1w + 1z \geq 600$$

$$1x + 0y + 1w + 0z \leq 700$$

$$0x + 1y + 0w + 1z \leq 800$$

$$x \geq 0, y \geq 0, w \geq 0, z \geq 0$$

Linear Programming - Example

Linear Program - Matrix Representation

minimise $5x + 10y + 4w + 8z$

subject to $-1x - 1y + 0w + 0z \leq -400$

$$0x + 0y - 1w - 1z \leq -600$$

$$1x + 0y + 1w + 0z \leq 700$$

$$0x + 1y + 0w + 1z \leq 800$$

$$x \geq 0, y \geq 0, w \geq 0, z \geq 0$$

Linear Programming - Example

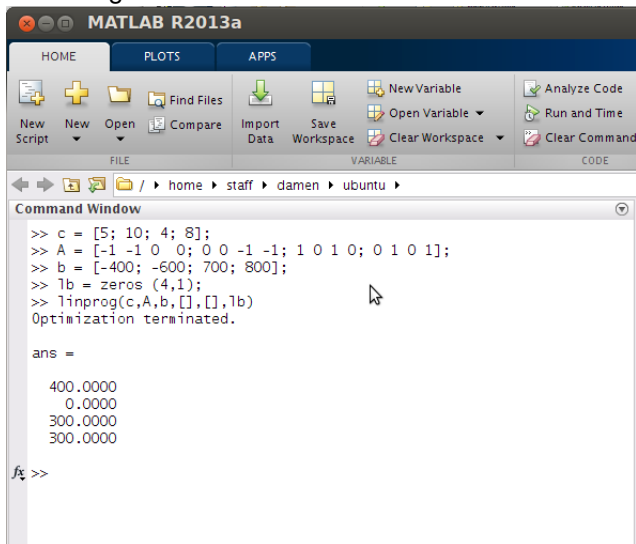

Linear Program - Matrix Representation

$$\mathbf{c} = \begin{bmatrix} 5 \\ 10 \\ 4 \\ 8 \end{bmatrix}, \mathbf{A} = \begin{bmatrix} -1 & -1 & 0 & 0 \\ 0 & 0 & -1 & -1 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \end{bmatrix}, \mathbf{b} = \begin{bmatrix} -400 \\ -600 \\ 700 \\ 800 \end{bmatrix}, \mathbf{x} = \begin{bmatrix} x \\ y \\ w \\ z \end{bmatrix}$$

minimise	$\mathbf{c}^T \mathbf{x}$
<i>subject to</i>	$\mathbf{Ax} \leq \mathbf{b}$
	$\mathbf{x} \geq 0$

Linear Programming - Example

Can be solved using a linear solver

The image shows the MATLAB R2013a interface. The Command Window displays the following code and output:

```
>> c = [5; 10; 4; 8];  
>> A = [-1 -1 0 0; 0 0 -1 -1; 1 0 1 0; 0 1 0 1];  
>> b = [-400; -600; 700; 800];  
>> lb = zeros(4,1);  
>> linprog(c,A,b,[],[],lb)  
Optimization terminated.  
  
ans =  
  
    400.0000  
     0.0000  
    300.0000  
    300.0000
```

The output shows the optimal values for the variables, with the first variable at 400, the second at 0, and the third and fourth at 300.

Linear Programming

In two dimensions...

- ▶ A linear equation defines a line in space $5x + 2y = 7$

Linear Programming

In two dimensions...

- ▶ A linear **inequality** defines a half-space $5x + 2y \geq 7$

Linear Programming

In two dimensions...

- ▶ Multiple linear inequalities constrain the space of solutions
- ▶ Setting the variables x and y to values that satisfy all constraints results in a **feasible** solution
- ▶ Setting the variables x and y to values that fail to satisfy any constraint results in an **infeasible** solution
- ▶ The shaded area represents the space of **feasible** solutions

Linear Programming

- ▶ When the set of inequalities represent a convex hull in space, the feasible region is said to be **bounded**

Linear Programming

In two dimensions...

- ▶ If the linear program has no feasible solution, the linear program is said to be **infeasible**

e.g.

$$5x + 2y \geq 7$$

$$x \leq 0$$

$$y \leq 0$$

- ▶ If a linear program has some feasible solutions but does not have a finite optimal objective value, it is said to be **unbounded**

Linear Programming

In two dimensions...

- For the linear program

$$\begin{array}{ll}\text{minimise} & x - y \\ \text{subject to} & 5x + 2y \geq 7 \\ & -3x + y \leq 4 \\ & 8x + y \leq 24\end{array}$$

- The search is for a feasible solution that minimises the **objective function** $x - y$

Linear Programming

In two dimensions...

- The objective function takes different values within the feasible region

Linear Programming

In two dimensions...

- The objective function takes different values within the feasible region

Linear Programming

In two dimensions...

- The objective function takes different values within the feasible region

Linear Programming

In two dimensions...

- ▶ It is no accident that the optimal solution to the linear program occurs at a vertex of the feasible solution.

Linear Programming

In two dimensions...

- ▶ It is no accident that the optimal solution to the linear program occurs at a vertex of the feasible solution.
- ▶ The optimal value must be at the boundary of the feasible region

Linear Programming

In two dimensions...

- ▶ It is no accident that the optimal solution to the linear program occurs at a vertex of the feasible solution.
- ▶ The optimal value must be at the boundary of the feasible region
- ▶ The intersection is thus either a single vertex or a line segment (that contains two vertices)

Linear Programming

In two dimensions...

- ▶ It is no accident that the optimal solution to the linear program occurs at a vertex of the feasible solution.
- ▶ The optimal value must be at the boundary of the feasible region
- ▶ The intersection is thus either a single vertex or a line segment (that contains two vertices)
- ▶ Eureka... calculate the objective function at all vertices!

Linear Programming

In two dimensions...

- ▶ It is no accident that the optimal solution to the linear program occurs at a vertex of the feasible solution.
- ▶ The optimal value must be at the boundary of the feasible region
- ▶ The intersection is thus either a single vertex or a line segment (that contains two vertices)
- ▶ Eureka... calculate the objective function at all vertices!
- ▶ But... we cannot easily graph linear programs in 3+ dimensions

Max-Flow as a Linear Program

Max-flow problem can be formulated as a linear program

EXAMPLE

Objective function maximise $f_1 + f_2$

Constraints

Ensure the flow is
feasible.

$$f_1 \leq c_1$$

$$f_2 \leq c_2$$

$$f_3 \leq c_3$$

$$f_4 \leq c_4$$

$$f_5 \leq c_5$$

Conservation
constraints.

$$f_1 + f_3 - f_4 = 0$$

$$f_2 - f_3 - f_5 = 0$$

$$f_1, f_2, f_3, f_4, f_5 \geq 0$$

The Simplex Algorithm

- ▶ Takes as input a linear program and returns an optimal solution
- ▶ It starts at some vertex and performs a sequence of iterations
- ▶ In each iteration, it moves along an edge to a neighbouring vertex whose objective value is smaller than the current vertex
- ▶ Terminates when it reaches a local optimum
- ▶ As the vertex is a convex hull, the local optimum is actually a global optimum

Simplex Algorithm - Standard Form

The standard form to solve a simplex algorithm is:

$$\text{maximise} \quad \sum_{j=1}^n c_j x_j$$

$$\text{subject to} \quad \sum_{j=1}^n a_{ij} x_j \leq b_i \quad \text{for } i = 1, 2, \dots, m$$

$$x_j \geq 0 \quad \text{for } j = 1, 2, \dots, n$$

The Simplex Algorithm - Standard Form

A linear function is in non-standard form for the Simplex algorithm if

- ▶ The objective function is a minimisation rather than a maximisation
- ▶ There might be variables without nonnegativity constraints
- ▶ There might be equality rather than inequality constraints
- ▶ There might be inequality constraints with an opposite sign

The Simplex Algorithm - Standard Form

To convert to a standard form:

- If the objective function is a minimisation \rightarrow negate the coefficients
e.g.

$$\text{minimise } -2x + 3y$$

becomes

$$\text{maximise } 2x - 3y$$

The Simplex Algorithm - Standard Form

To convert to a standard form:

- If a variable y does not have a non-negativity constraint \rightarrow change y to $y_1 - y_2$ and add $y_1 \geq 0, y_2 \geq 0$
e.g.

$$\begin{array}{ll}\text{maximise} & 2x - 3y \\ \text{subject to} & x + y \leq 7 \\ & x - y \leq 4 \\ & x \geq 0\end{array}$$

\rightarrow

$$\begin{array}{ll}\text{maximise} & 2x - 3y_1 + 3y_2 \\ \text{subject to} & x + y_1 - y_2 \leq 7 \\ & x - y_1 + y_2 \leq 4 \\ & x, y_1, y_2 \geq 0\end{array}$$

The Simplex Algorithm - Standard Form

To convert to a standard form:

- If equality constraint exists \rightarrow replace by two inequalities $\leq b$ and $\geq b$
e.g.

maximise	$2x - 3y$
subject to	$x + y = 7$
	..

\rightarrow

maximise	$2x - 3y$
subject to	$x + y \leq 7$
	$x + y \geq 7$
	..

The Simplex Algorithm - Standard Form

To convert to a standard form:

- If inequality constraint needs to change sign \rightarrow negate
e.g.

$$\begin{array}{ll}\text{maximise} & 2x - 3y \\ \text{subject to} & x + y \geq 7 \\ & ..\end{array}$$

\rightarrow

$$\begin{array}{ll}\text{maximise} & 2x - 3y \\ \text{subject to} & -x - y \leq -7 \\ & ..\end{array}$$

The Simplex Algorithm - Standard Form

e.g. convert the following linear program into standard form:

minimise	$2x_1 + 7x_2 + x_3$
subject to	$x_1 - x_3 = 7$
	$3x_1 + x_2 \geq 24$
	$x_2 \geq 0$
	$x_3 \leq 0$

The Simplex Algorithm - Slack Form

In addition to being in the standard form, the Simplex algorithm requires the linear program to be in the slack form.

$$z = v + \sum_{j=1}^n c_j x_j$$

$$x_{n+i} = b_i - \sum_{j=1}^n a_{ij} x_j \quad \text{for } i = 1, 2, \dots, m$$

$$x_i \geq 0 \quad \text{for } i = 1, 2, \dots, n + m$$

The Simplex Algorithm - Slack Form

- ▶ For each inequality $\sum_{j=1}^n a_{ij}x_j \leq b_i$
- ▶ Introduce a new variable s (called the **slack variable** because it measures the difference between the left and the right hand sides of the equation.)
- ▶ Rewrite the inequality $s = b_i - \sum_{j=1}^n a_{ij}x_j$
- ▶ Add a non-negativity constraint $s \geq 0$

The Simplex Algorithm - Slack Form

e.g. convert the following linear program from standard form to slack form:

maximise	$2x_1 - 3x_2 + 3x_3$
subject to	$x_1 + x_2 - x_3 \leq 7$
	$-x_1 - x_2 + x_3 \leq -7$
	$x_1 - 2x_2 + 2x_3 \leq 4$
	$x_1, x_2, x_3 \geq 0$

The Simplex Algorithm - Slack Form

- ▶ Step 1: add the slack variables
- ▶ Step 2: Replace the objective function value by z

$$\begin{aligned}z &= 2x_1 - 3x_2 + 3x_3 \\x_4 &= 7 - x_1 - x_2 + x_3 \\x_5 &= -7 - x_1 + x_2 - x_3 \\x_6 &= 4 - x_1 + 2x_2 - 2x_3 \\x_1, x_2, x_3, x_4, x_5, x_6 &\geq 0\end{aligned}$$

The Simplex Algorithm - Slack Form

- ▶ Step 1: add the slack variables
- ▶ Step 2: Replace the objective function value by z

$$\begin{aligned}z &= 2x_1 - 3x_2 + 3x_3 \\x_4 &= 7 - x_1 - x_2 + x_3 \\x_5 &= -7 - x_1 + x_2 - x_3 \\x_6 &= 4 - x_1 + 2x_2 - 2x_3 \\x_1, x_2, x_3, x_4, x_5, x_6 &\geq 0\end{aligned}$$

- ▶ The variables on the left hand side of equalities are called **basic variables**
- ▶ The variables on the right hand side of equalities are called **nonbasic variables**

The Simplex Algorithm - Basic Solution

- ▶ A feasible solution can be found by setting all nonbasic variables (right-hand side variables) to 0
- ▶ This is a feasible solution and is a *vertex* in the convex hull because of the non-negativity constraint.
- ▶ For the example below, $\mathbf{x} = (0, 0, 0, 30, 24, 36)$ and $z = 0$
- ▶ This is referred to as a basic feasible solution

Z	$=$		$3x_1$	$+$	x_2	$+$	$2x_3$	(1)
x_4	$=$	30	$-x_1$	$-x_2$	$-3x_3$			(2)
x_5	$=$	24	$-2x_1$	$-2x_2$	$-5x_3$			(3)
x_6	$=$	36	$-4x_1$	$-x_2$	$-2x_3$			(4)

The Simplex Algorithm - Iteration

- ▶ At each iteration in the simplex algorithm, we select a non-basic variable x_i
- ▶ This chosen variable should have a positive coefficient in the objective function
- ▶ So that increasing its value would increase the objective function
- ▶ Let's choose x_1

Z	$=$		$3x_1$	$+$	x_2	$+$	$2x_3$	(1)
x_4	$=$	30	$-x_1$	$-$	x_2	$-$	$3x_3$	(2)
x_5	$=$	24	$-2x_1$	$-$	$2x_2$	$-$	$5x_3$	(3)
x_6	$=$	36	$-4x_1$	$-$	x_2	$-$	$2x_3$	(4)

The Simplex Algorithm - Iteration

- We try to increase x_1 as much as possible without increasing any non-negativity constraint

Z	$=$		$3x_1$	$+$	x_2	$+$	$2x_3$	(1)
x_4	$=$	30	$-x_1$	$-$	x_2	$-$	$3x_3$	(2)
x_5	$=$	24	$-2x_1$	$-$	$2x_2$	$-$	$5x_3$	(3)
x_6	$=$	36	$-4x_1$	$-$	x_2	$-$	$2x_3$	(4)

The Simplex Algorithm - Iteration

- ▶ We try to increase x_1 as much as possible without increasing any non-negativity constraint
 - ▶ In (2), x_1 could be set to 30 max
 - ▶ In (3), x_1 could be set to 12 max
 - ▶ In (4), x_1 could be set to 9 max

Z	$=$		$3x_1$	$+$	x_2	$+$	$2x_3$	(1)
x_4	$=$	30	$-x_1$	$-$	x_2	$-$	$3x_3$	(2)
x_5	$=$	24	$-2x_1$	$-$	$2x_2$	$-$	$5x_3$	(3)
x_6	$=$	36	$-4x_1$	$-$	x_2	$-$	$2x_3$	(4)

The Simplex Algorithm - Iteration

- ▶ We try to increase x_1 as much as possible without increasing any non-negativity constraint
 - ▶ In (2), x_1 could be set to 30 max
 - ▶ In (3), x_1 could be set to 12 max
 - ▶ In (4), x_1 could be set to 9 max
- ▶ Equation (4) is the tightest constraint
- ▶ We therefore switch the roles of x_1 and x_6

Z	$=$		$3x_1$	$+$	x_2	$+$	$2x_3$	(1)
x_4	$=$	30	$-x_1$	$-$	x_2	$-$	$3x_3$	(2)
x_5	$=$	24	$-2x_1$	$-$	$2x_2$	$-$	$5x_3$	(3)
x_6	$=$	36	$-4x_1$	$-$	x_2	$-$	$2x_3$	(4)

The Simplex Algorithm - Iteration

- We re-arrange (4) so $x_1 = 9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4}$

The Simplex Algorithm - Iteration

- ▶ We re-arrange (4) so $x_1 = 9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4}$
- ▶ x_1 will be replaced by x_6 on the right-hand side of Equations 1-3

Z	$=$	$+$	$3(9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4})$	$+$	x_2	$+$	$2x_3$	(1)
x_4	$=$	30	$- (9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4})$	$-$	x_2	$-$	$3x_3$	(2)
x_5	$=$	24	$- 2(9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4})$	$-$	$2x_2$	$-$	$5x_3$	(3)
x_1	$=$	9	$- \frac{x_2}{4}$	$-$	$\frac{x_3}{2}$	$-$	$\frac{x_6}{4}$	(4)

The Simplex Algorithm - Iteration

$$z = 27 + \frac{x_2}{4} + \frac{x_3}{2} - \frac{3x_6}{4} \quad (1)$$

$$x_1 = 9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4} \quad (2)$$

$$x_4 = 21 - \frac{3x_2}{4} - \frac{5x_3}{2} + \frac{x_6}{4} \quad (3)$$

$$x_5 = 6 - \frac{3x_2}{2} - 4x_3 + \frac{x_6}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- After this operation the basic variables become (x_1 , x_4 and x_5)

$$Z = 27 + \frac{x_2}{4} + \frac{x_3}{2} - \frac{3x_6}{4} \quad (1)$$

$$x_1 = 9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4} \quad (2)$$

$$x_4 = 21 - \frac{3x_2}{4} - \frac{5x_3}{2} + \frac{x_6}{4} \quad (3)$$

$$x_5 = 6 - \frac{3x_2}{2} - 4x_3 + \frac{x_6}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ After this operation the basic variables become (x_1 , x_4 and x_5)
- ▶ The solution just changes to be (9,0,0,21,6,0) and the objective function increases to 27

$$Z = 27 + \frac{x_2}{4} + \frac{x_3}{2} - \frac{3x_6}{4} \quad (1)$$

$$x_1 = 9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4} \quad (2)$$

$$x_4 = 21 - \frac{3x_2}{4} - \frac{5x_3}{2} + \frac{x_6}{4} \quad (3)$$

$$x_5 = 6 - \frac{3x_2}{2} - 4x_3 + \frac{x_6}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ After this operation the basic variables become (x_1 , x_4 and x_5)
- ▶ The solution just changes to be (9,0,0,21,6,0) and the objective function increases to 27
- ▶ This too is a vertex in the convex hull

$$Z = 27 + \frac{x_2}{4} + \frac{x_3}{2} - \frac{3x_6}{4} \quad (1)$$

$$x_1 = 9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4} \quad (2)$$

$$x_4 = 21 - \frac{3x_2}{4} - \frac{5x_3}{2} + \frac{x_6}{4} \quad (3)$$

$$x_5 = 6 - \frac{3x_2}{2} - 4x_3 + \frac{x_6}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ This operation is known as a **pivot**, which exchanges the positions of one nonbasic variable (called the **entering variable**) and one basic variable (called the **leaving variable**)
- ▶ Next we choose another entering variable (we can choose x_2 or x_3 and let's choose x_3)

$$z = 27 + \frac{x_2}{4} + \frac{x_3}{2} - \frac{3x_6}{4} \quad (1)$$

$$x_1 = 9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4} \quad (2)$$

$$x_4 = 21 - \frac{3x_2}{4} - \frac{5x_3}{2} + \frac{x_6}{4} \quad (3)$$

$$x_5 = 6 - \frac{3x_2}{2} - 4x_3 + \frac{x_6}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ We try to increase x_3 as much as possible without increasing any non-negativity constraint

The Simplex Algorithm - Iteration

- ▶ We try to increase x_3 as much as possible without increasing any non-negativity constraint
 - ▶ In (2), x_3 could be set to 18 max
 - ▶ In (3), x_3 could be set to 8.4 max
 - ▶ In (4), x_3 could be set to 1.5 max

The Simplex Algorithm - Iteration

- ▶ We try to increase x_3 as much as possible without increasing any non-negativity constraint
 - ▶ In (2), x_3 could be set to 18 max
 - ▶ In (3), x_3 could be set to 8.4 max
 - ▶ In (4), x_3 could be set to 1.5 max
- ▶ Equation (4) is the tightest constraint
- ▶ We therefore switch the roles of x_3 and x_5

The Simplex Algorithm - Iteration

- ▶ We try to increase x_3 as much as possible without increasing any non-negativity constraint
 - ▶ In (2), x_3 could be set to 18 max
 - ▶ In (3), x_3 could be set to 8.4 max
 - ▶ In (4), x_3 could be set to 1.5 max
- ▶ Equation (4) is the tightest constraint
- ▶ We therefore switch the roles of x_3 and x_5
- ▶ $x_3 = \frac{3}{2} - \frac{3x_2}{8} - \frac{x_5}{4} + \frac{x_6}{8}$

$$Z = 27 + \frac{x_2}{4} + \frac{x_3}{2} - \frac{3x_6}{4} \quad (1)$$

$$x_1 = 9 - \frac{x_2}{4} - \frac{x_3}{2} - \frac{x_6}{4} \quad (2)$$

$$x_3 = \frac{3}{2} - \frac{3x_2}{8} - \frac{x_5}{4} + \frac{x_6}{8} \quad (3)$$

$$x_4 = 21 - \frac{3x_2}{4} - \frac{5x_3}{2} + \frac{x_6}{4} \quad (4)$$

The Simplex Algorithm - Iteration

- The current solution is $(33/4, 0, 3/2, 69/4, 0, 0)$ with the objective value $111/4$

$$Z = \frac{111}{4} + \frac{x_2}{16} - \frac{x_5}{8} - \frac{11x_6}{16} \quad (1)$$

$$x_1 = \frac{33}{4} - \frac{x_2}{16} + \frac{x_5}{8} - \frac{5x_6}{16} \quad (2)$$

$$x_3 = \frac{3}{2} - \frac{3x_2}{8} - \frac{x_5}{4} + \frac{x_6}{8} \quad (3)$$

$$x_4 = \frac{69}{4} + \frac{3x_2}{16} + \frac{5x_5}{8} - \frac{x_6}{16} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ The current solution is $(33/4, 0, 3/2, 69/4, 0, 0)$ with the objective value $111/4$
- ▶ Next we increase x_2 by substituting it with x_3

$$Z = \frac{111}{4} + \frac{x_2}{16} - \frac{x_5}{8} - \frac{11x_6}{16} \quad (1)$$

$$x_1 = \frac{33}{4} - \frac{x_2}{16} + \frac{x_5}{8} - \frac{5x_6}{16} \quad (2)$$

$$x_3 = \frac{3}{2} - \frac{3x_2}{8} - \frac{x_5}{4} + \frac{x_6}{8} \quad (3)$$

$$x_4 = \frac{69}{4} + \frac{3x_2}{16} + \frac{5x_5}{8} - \frac{x_6}{16} \quad (4)$$

The Simplex Algorithm - Iteration

- The current solution is (8,4, 0, 18, 0, 0) with the objective value 28

$$Z = 28 - \frac{x_3}{6} - \frac{x_5}{6} - \frac{2x_6}{3} \quad (1)$$

$$x_1 = 8 + \frac{x_6}{6} + \frac{x_5}{6} - \frac{x_6}{3} \quad (2)$$

$$x_2 = 4 - \frac{8x_3}{3} - \frac{2x_5}{3} + \frac{x_6}{3} \quad (3)$$

$$x_4 = 18 - \frac{x_3}{2} + \frac{x_5}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ The current solution is (8,4, 0, 18, 0, 0) with the objective value 28
- ▶ In the original linear program $x_1 = 8$, $x_2 = 4$ and $x_3 = 0$, with the objective value = 28

$$z = 28 - \frac{x_3}{6} - \frac{x_5}{6} - \frac{2x_6}{3} \quad (1)$$

$$x_1 = 8 + \frac{x_6}{6} + \frac{x_5}{6} - \frac{x_6}{3} \quad (2)$$

$$x_2 = 4 - \frac{8x_3}{3} - \frac{2x_5}{3} + \frac{x_6}{3} \quad (3)$$

$$x_4 = 18 - \frac{x_3}{2} + \frac{x_5}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ The current solution is (8,4, 0, 18, 0, 0) with the objective value 28
- ▶ In the original linear program $x_1 = 8$, $x_2 = 4$ and $x_3 = 0$, with the objective value = 28
- ▶ The slack variables measure how much slack remains within each inequality

$$z = 28 - \frac{x_3}{6} - \frac{x_5}{6} - \frac{2x_6}{3} \quad (1)$$

$$x_1 = 8 + \frac{x_6}{6} + \frac{x_5}{6} - \frac{x_6}{3} \quad (2)$$

$$x_2 = 4 - \frac{8x_3}{3} - \frac{2x_5}{3} + \frac{x_6}{3} \quad (3)$$

$$x_4 = 18 - \frac{x_3}{2} + \frac{x_5}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ The current solution is (8,4, 0, 18, 0, 0) with the objective value 28
- ▶ In the original linear program $x_1 = 8$, $x_2 = 4$ and $x_3 = 0$, with the objective value = 28
- ▶ The slack variables measure how much slack remains within each inequality
- ▶ All non-basic variables have a negative coefficient in the objective function

$$z = 28 - \frac{x_3}{6} - \frac{x_5}{6} - \frac{2x_6}{3} \quad (1)$$

$$x_1 = 8 + \frac{x_6}{6} + \frac{x_5}{6} - \frac{x_6}{3} \quad (2)$$

$$x_2 = 4 - \frac{8x_3}{3} - \frac{2x_5}{3} + \frac{x_6}{3} \quad (3)$$

$$x_4 = 18 - \frac{x_3}{2} + \frac{x_5}{2} \quad (4)$$

The Simplex Algorithm - Iteration

- ▶ The current solution is (8,4, 0, 18, 0, 0) with the objective value 28
- ▶ In the original linear program $x_1 = 8$, $x_2 = 4$ and $x_3 = 0$, with the objective value = 28
- ▶ The slack variables measure how much slack remains within each inequality
- ▶ All non-basic variables have a negative coefficient in the objective function
- ▶ The vertex with the maximum value is reached — terminate

$$z = 28 - \frac{x_3}{6} - \frac{x_5}{6} - \frac{2x_6}{3} \quad (1)$$

$$x_1 = 8 + \frac{x_6}{6} + \frac{x_5}{6} - \frac{x_6}{3} \quad (2)$$

$$x_2 = 4 - \frac{8x_3}{3} - \frac{2x_5}{3} + \frac{x_6}{3} \quad (3)$$

$$x_4 = 18 - \frac{x_3}{2} + \frac{x_5}{2} \quad (4)$$

The Simplex Algorithm

$(N, B, A, b, c, v) = \text{SIMPLEX}(A, b, c);$

- convert to slack form (N: nonbasic variable, B: basic variable)

The Simplex Algorithm

```
(N,B,A,b,c,v) = SIMPLEX (A,b,c);  
while some index  $j \in N$  has  $c_j > 0$  do
```

- ▶ convert to slack form (N: nonbasic variable, B: basic variable)
- ▶ find a nonbasic variable that can increase the objective value

```
end
```

The Simplex Algorithm

```
(N,B,A,b,c,v) = SIMPLEX (A,b,c);  
while some index  $j \in N$  has  $c_j > 0$  do  
  for each  $i \in B$  do  
     $\Delta_i = b_i/a_{ij}$ ;  
  end
```

end

- ▶ convert to slack form (N: nonbasic variable, B: basic variable)
- ▶ find a nonbasic variable that can increase the objective value

The Simplex Algorithm

```
(N,B,A,b,c,v) = SIMPLEX (A,b,c);  
while some index  $j \in N$  has  $c_j > 0$  do  
  for each  $i \in B$  do  
     $\Delta_i = b_i/a_{ij}$ ;  
  end  
  choose  $l \in B$  that minimises  $\Delta_l$ ;  
  
end
```

- ▶ convert to slack form (N: nonbasic variable, B: basic variable)
- ▶ find a nonbasic variable that can increase the objective value
- ▶ find the tight basic variable

The Simplex Algorithm

```
(N,B,A,b,c,v) = SIMPLEX (A,b,c);  
while some index  $j \in N$  has  $c_j > 0$  do  
  for each  $i \in B$  do  
     $\Delta_i = b_i/a_{ij}$ ;  
  end  
  choose  $l \in B$  that minimises  $\Delta_l$ ;  
  if  $\Delta_l == \inf$  then  
    return "unbounded"  
  else  
    (N,B,A,b,c,v) = PIVOT(N,B,A,b,c,v,l,e)  
  end  
end
```

- ▶ convert to slack form (N: nonbasic variable, B: basic variable)
- ▶ find a nonbasic variable that can increase the objective value
- ▶ find the tight basic variable
- ▶ replace the nonbasic with the basic variable

The Simplex Algorithm

```
(N,B,A,b,c,v) = SIMPLEX (A,b,c);  
while some index  $j \in N$  has  $c_j > 0$  do  
  for each  $i \in B$  do  
     $\Delta_i = b_i/a_{ij}$ ;  
  end  
  choose  $l \in B$  that minimises  $\Delta_l$ ;  
  if  $\Delta_l == \inf$  then  
    return "unbounded"  
  else  
    (N,B,A,b,c,v) = PIVOT(N,B,A,b,c,v,l,e)  
  end  
end  
for  $i=1..n$  do  
  if  $i \in B$  then  
     $\bar{x}_i = b_i$   
  else  
     $\bar{x}_i = 0$   
  end  
end  
return  $(\bar{x}_1, \bar{x}_2, \dots, \bar{x}_n)$ 
```

- ▶ convert to slack form (N: nonbasic variable, B: basic variable)
- ▶ find a nonbasic variable that can increase the objective value
- ▶ find the tight basic variable
- ▶ replace the nonbasic with the basic variable
- ▶ find the values of the original variables
- ▶ return the values of original variables

Example

Solve the following linear program using the Simplex Algorithm

$$\begin{array}{ll}\text{maximise} & 18x_1 + 12.5x_2 \\ \text{subject to} & x_1 + x_2 \leq 20 \\ & x_1 \leq 12 \\ & x_2 \leq 16 \\ & x_1, x_2 \geq 0\end{array}$$
